

Docket No. AUS990938US1

HYPERVISOR VIRTUALIZATION OF OS CONSOLE AND OPERATOR PANEL

BACKGROUND OF THE INVENTION

5

1. Technical Field:

The present invention relates generally to the field of computer architecture and, more specifically, to methods and systems for allowing multiple operating
10 system images within a logically partitioned data processing system to interact with a console and operator panel.

2. Description of Related Art:

15 A logical partitioning option (LPAR) within a data processing system allows multiple copies of a single operating system (OS) or multiple heterogeneous operating systems to be simultaneously run on a single data processing system platform. A partition, within which an
20 operating system image runs, is assigned a non-overlapping sub-set of the platform's resources. These platform allocable resources include one or more architecturally distinct processors with their interrupt management area, regions of system memory, and I/O
25 adapter bus slots. The partition's resources are represented by its own open firmware device tree to the OS image.

Each distinct OS or image of an OS running within the platform are protected from each other such that
30 software errors on one logical partition cannot affect the correct operation of any of the other partitions.

Docket No. AUS990938US1

This is provided by allocating a disjoint set of platform resources to be directly managed by each OS image and by providing mechanisms for ensuring that the various images cannot control any resources that have not been allocated to it. Furthermore, software errors in the control of an OS's allocated resources are prevented from affecting the resources of any other image. Thus, each image of the OS (or each different OS) directly controls a distinct set of allocable resources within the platform.

10 There are certain resources within many server platforms that exist singly, yet each distinct OS within the platform must interact with these resources. For example, the RS/6000, a product of International Business Machines Corporation of Armonk, New York, includes a
15 console and an operator panel for allowing a system administrator to detect and correct problems within the platform. However, each of these resources exists singly within the platform and it is impractical to duplicate these resources. While present architectures often do
20 not preclude the sharing of allocable resources of this type between partitions, there is no current architectural support for such sharing. Therefore, a method, system, and computer program product for providing the sharing of allocable resources within a
25 logically partitioned platform is desirable.

Docket No. AUS990938US1

SUMMARY OF THE INVENTION

5 The present invention provides a logically
partitioned data processing system in which shared
resources are emulated to provide each partition a
separate copy of the shared resource. In one embodiment,
the logically partitioned data processing system includes
10 a plurality of logical partitions, a plurality of
operating systems executing within the data processing
system and a plurality of assignable resources. Each of
the plurality of operating systems is assigned to a
separate one of the plurality of logical partitions, such
15 that no more than one operating system is assigned to any
given logical partition. Each of the plurality of
assignable resources is assigned to a single one of the
plurality of logical partitions. The logically
partitioned data processing system also includes a
20 hypervisor. The hypervisor emulates shared resources,
such as an operator panel and a system console, and
provides a virtual copy of these shared resources to each
of the plurality of logical partitions.

BRIEF DESCRIPTION OF THE DRAWINGS

5 The novel features believed characteristic of the invention are set forth in the appended claims. The invention itself, however, as well as a preferred mode of use, further objectives and advantages thereof, will best be understood by reference to the following detailed
10 description of an illustrative embodiment when read in conjunction with the accompanying drawings, wherein:

Figure 1 depicts a pictorial representation of a distributed data processing system in which the present invention may be implemented;

15 **Figure 2**, a block diagram of a data processing system in accordance with the present invention is illustrated;

Figure 3 depicts a block diagram of a data processing system, which may be implemented as a
20 logically partitioned server, in accordance with the present invention;

Figure 4 depicts a block diagram illustrating a prior art logically partitioned platform in accordance with the present invention;

25 **Figure 5** depicts a block diagram of a logically partitioned platform in which the present invention may be implemented;

Figures 6A-6B depict high-level flowcharts illustrating exemplary processes, performed for example,
30 in hypervisor **510**, for emulating a console and operator platform in accordance with the present invention;

Docket No. AUS990938US1

Figure 7 depicts a high level flowchart illustrating an exemplary process on a hardware system console for presenting the information from the various OS images to an operator in accordance with the present invention; and

5 **Figure 8** depicts a high level flowchart illustrating an exemplary process on a hardware system console for sending messages to various ones of multiple OS images running on a logically partitioned platform in accordance with the present invention.

10

Docket No. AUS990938US1

DETAILED DESCRIPTION OF THE PREFERRED EMBODIMENT

5 With reference now to the figures, and in particular with reference to **Figure 1**, a pictorial representation of a distributed data processing system is depicted in which the present invention may be implemented.

10 Distributed data processing system **100** is a network of computers in which the present invention may be implemented. Distributed data processing system **100** contains network **102**, which is the medium used to provide communications links between various devices and computers connected within distributed data processing
15 system **100**. Network **102** may include permanent connections, such as wire or fiber optic cables, or temporary connections made through telephone connections.

 In the depicted example, server **104** is connected to hardware system console **150**. Server **104** is also
20 connected to network **102**, along with storage unit **106**. In addition, clients **108**, **110** and **112** are also connected to network **102**. These clients, **108**, **110** and **112**, may be, for example, personal computers or network computers. For purposes of this application, a network computer is
25 any computer coupled to a network that receives a program or other application from another computer coupled to the network. In the depicted example, server **104** is a logically partitioned platform and provides data, such as boot files, operating system images and applications, to
30 clients **108-112**. Hardware system console **150** may be a laptop computer and is used to display messages to an

Docket No. AUS990938US1

operator from each operating system image running on server 104, as well as to send input information, received from the operator, to server 104. Clients 108, 110 and 112 are clients to server 104. Distributed data processing system 100 may include additional servers, clients, and other devices not shown. Distributed data processing system 100 also includes printers 114, 116 and 118. A client, such as client 110, may print directly to printer 114. Clients such as client 108 and client 112 do not have directly attached printers. These clients may print to printer 116, which is attached to server 104, or to printer 118, which is a network printer that does not require connection to a computer for printing documents. Client 110, alternatively, may print to printer 116 or printer 118, depending on the printer type and the document requirements.

In the depicted example, distributed data processing system 100 is the Internet, with network 102 representing a worldwide collection of networks and gateways that use the TCP/IP suite of protocols to communicate with one another. At the heart of the Internet is a backbone of high-speed data communication lines between major nodes or host computers consisting of thousands of commercial, government, education, and other computer systems that route data and messages. Of course, distributed data processing system 100 also may be implemented as a number of different types of networks such as, for example, an intranet or a local area network.

Figure 1 is intended as an example and not as an architectural limitation for the processes of the present

Docket No. AUS990938US1

invention.

With reference now to **Figure 2**, a block diagram of a data processing system in accordance with the present invention is illustrated. Data processing system **200** is an example of a hardware system console, such as hardware system console **150** depicted in **Figure 1**. Data processing system **200** employs a peripheral component interconnect (PCI) local bus architecture. Although the depicted example employs a PCI bus, other bus architectures, such as Micro Channel and ISA, may be used. Processor **202** and main memory **204** are connected to PCI local bus **206** through PCI bridge **208**. PCI bridge **208** may also include an integrated memory controller and cache memory for processor **202**. Additional connections to PCI local bus **206** may be made through direct component interconnection or through add-in boards. In the depicted example, local area network (LAN) adapter **210**, SCSI host bus adapter **212**, and expansion bus interface **214** are connected to PCI local bus **206** by a direct component connection. In contrast, audio adapter **216**, graphics adapter **218**, and audio/video adapter (A/V) **219** are connected to PCI local bus **206** by add-in boards inserted into expansion slots. Expansion bus interface **214** provides a connection for a keyboard and mouse adapter **220**, modem **222**, and additional memory **224**. In the depicted example, SCSI host bus adapter **212** provides a connection for hard disk drive **226**, tape drive **228**, CD-ROM drive **230**, and digital video disc read only memory drive (DVD-ROM) **232**. Typical PCI local bus implementations will support three or four PCI expansion slots or add-in connectors.

Docket No. AUS990938US1

An operating system runs on processor 202 and is used to coordinate and provide control of various components within data processing system 200 in **Figure 2**. The operating system may be a commercially available
5 operating system, such as OS/2, which is available from International Business Machines Corporation. "OS/2" is a trademark of International Business Machines Corporation. An object-oriented programming system, such as Java, may run in conjunction with the operating system, providing
10 calls to the operating system from Java programs or applications executing on data processing system 200. Instructions for the operating system, the object-oriented operating system, and applications or programs are located on a storage device, such as hard
15 disk drive 226, and may be loaded into main memory 204 for execution by processor 202.

Those of ordinary skill in the art will appreciate that the hardware in **Figure 2** may vary depending on the implementation. For example, other peripheral devices,
20 such as optical disk drives and the like, may be used in addition to or in place of the hardware depicted in **Figure 2**. The depicted example is not meant to imply architectural limitations with respect to the present invention. For example, the processes of the present
25 invention may be applied to multiprocessor data processing systems.

With reference now to **Figure 3**, a block diagram of a data processing system, which may be implemented as a logically partitioned server, such as server 104 in
30 **Figure 1**, is depicted in accordance with the present invention. Data processing system 300 may be a symmetric

Docket No. AUS990938US1

multiprocessor (SMP) system including a plurality of processors 301, 302, 303, and 304 connected to system bus 306. For example, data processing system 300 may be an IBM RS/6000, a product of International Business Machines Corporation in Armonk, New York. Alternatively, a single processor system may be employed. Also connected to system bus 306 is memory controller/cache 308, which provides an interface to a plurality of local memories 360-363. I/O bus bridge 310 is connected to system bus 306 and provides an interface to I/O bus 312. Memory controller/cache 308 and I/O bus bridge 310 may be integrated as depicted.

Data processing system 300 is a logically partitioned data processing system. Thus, data processing system 300 may have multiple heterogeneous operating systems (or multiple instances of a single operating system) running simultaneously. Each of these multiple operating systems may have any number of software programs executing within in it. Data processing system 300 is logically partitioned such that different I/O adapters 320-321, 328-329, 336-337, and 346-347 may be assigned to different logical partitions.

Thus, for example, suppose data processing system 300 is divided into three logical partitions, P1, P2, and P3. Each of I/O adapters 320-321, 328-329, and 336-337, each of processors 301-304, and each of local memories 360-363³ is assigned to one of the three partitions. For example, processor 301, memory 360, and I/O adapters 320, 328, and 329 may be assigned to logical partition P1; processors 302-303, memory 361, and I/O adapters 321 and

Docket No. AUS990938US1

337 may be assigned to partition P2; and processor 304, memories 362-363, and I/O adapters 336 and 346-347 may be assigned to logical partition P3.

Each operating system executing within data processing system 300 is assigned to a different logical partition. Thus, each operating system executing within data processing system 300 may access only those I/O units that are within its logical partition. Thus, for example, one instance of the Advanced Interactive Executive (AIX) operating system may be executing within partition P1, a second instance (image) of the AIX operating system may be executing within partition P2, and a Windows 2000™ operating system may be operating within logical partition P1. Windows 2000 is a product and trademark of Microsoft Corporation of Redmond, Washington.

Peripheral component interconnect (PCI) Host bridge 314 connected to I/O bus 312 provides an interface to PCI local bus 315. A number of Terminal Bridges 316-317 may be connected to PCI bus 315. Typical PCI bus implementations will support four Terminal Bridges for providing expansion slots or add-in connectors. Each of Terminal Bridges 316-317 is connected to a PCI/I/O Adapter 320-321 through a PCI Bus 318-319. Each I/O Adapter 320-321 provides an interface between data processing system 300 and input/output devices such as, for example, other network computers, which are clients to server 300. Only a single I/O adapter 320-321 may be connected to each terminal bridge 316-317. Each of terminal bridges 316-317 is configured to prevent the

Docket No. AUS990938US1

propagation of errors up into the PCI Host Bridge 314 and into higher levels of data processing system 300. By doing so, an error received by any of terminal bridges 316-317 is isolated from the shared buses 315 and 312 of the other I/O adapters 321, 328-329, and 336-337 that may be in different partitions. Therefore, an error occurring within an I/O device in one partition is not "seen" by the operating system of another partition. Thus, the integrity of the operating system in one partition is not effected by an error occurring in another logical partition. Without such isolation of errors, an error occurring within an I/O device of one partition may cause the operating systems or application programs of another partition to cease to operate or to cease to operate correctly.

Additional PCI host bridges 322, 330, and 340 provide interfaces for additional PCI buses 323, 331, and 341. Each of additional PCI buses 323, 331, and 341 are connected to a plurality of terminal bridges 324-325, 332-333, and 342-343 which are each connected to a PCI I/O adapter 328-329, 336-337, and 346-347 by a PCI bus 326-327, 334-335, and 344-345. Thus, additional I/O devices, such as, for example, modems or network adapters may be supported through each of PCI I/O adapters 328-329, 336-337, and 346-347. In this manner, server 300 allows connections to multiple network computers. A memory mapped graphics adapter 348 and hard disk 350 may also be connected to I/O bus 312 as depicted, either directly or indirectly. Hard disk 350 may be logically partitioned between various partitions without the need

Docket No. AUS990938US1

for additional hard disks. However, additional hard disks may be utilized if desired.

Those of ordinary skill in the art will appreciate that the hardware depicted in **Figure 3** may vary. For example, other peripheral devices, such as optical disk drives and the like, also may be used in addition to or in place of the hardware depicted. The depicted example is not meant to imply architectural limitations with respect to the present invention.

10 With reference now to **Figure 4**, a block diagram illustrating a prior art logically partitioned platform is depicted in accordance with the present invention. Logically partitioned platform **400** is an example of a platform that, in prior art systems, may have been
 15 implemented as server **104** in **Figure 1**. Logically partitioned platform **400** includes partitioned hardware **430**, shared single hardware **420**, and operating systems **402-408**. Operating systems **402-408** may be multiple copies of a single operating system or multiple
 20 heterogeneous operating systems simultaneously run on platform **400**.

Partitioned hardware **430** includes a plurality of processors **432-438**, a plurality of system memory units **440-446**, a plurality of input/output (I/O) adapters
 25 **448-462**, and a storage unit **470**. Each of the processors ~~442-448~~³, memory units **440-446**, and I/O adapters **448-462** may be assigned to one of multiple partitions within logically partitioned platform **400**, each of which corresponds to one of operating systems **402-408**.

30 Shared single hardware unit **420** includes console **422**

Docket No. AUS990938US1

and operator panel 424. Shared single hardware unit 420 may also include other shared devices not depicted in **Figure 4**. Console 422 typically includes a display and data entry device such as a keyboard. Console 422 allows
5 an operator to respond to and correct errors displayed on operator panel 424. Operator panel 424 is typically a panel display, such as an LCD display, on the front of the physical chassis of the server in which text messages are displayed alerting an operator of potential problems
10 within platform 400 or within a particular OS 402-408 running on platform 400.

Each operating system image 402-408 must share access to resources within shared single hardware 420. Therefore, some of the benefits of a logically
15 partitioned platform are lost, since each partition may access and change the contents of shared resources, thus affecting other partitions within the platform. One alternative to allowing each partition to share access to shared single hardware 420 is to duplicate these hardware
20 devices and have a separate operator panel and console for each partition. However, such a solution is bulky and, often cost prohibitive.

With reference now to **Figure 5**, a block diagram of an exemplary logically partitioned platform is depicted
25 in which the present invention may be implemented. The hardware in logically partitioned platform 500 may be implemented as, for example, server 200 in **Figure 2**. Logically partitioned platform 500 is similar to logically partitioned platform 400 in **Figure 4**. However,
30 Hypervisor 510, implemented as firmware, has been added.

Docket No. AUS990938US1

Firmware is "hard software" stored in a memory chip that holds its content without electrical power, such as, for example, read-only memory (ROM), programmable ROM (PROM), erasable programmable ROM (EPROM), electrically erasable
5 programmable ROM (EEPROM), and non-volatile random access memory (non-volatile RAM).

Hypervisor **510** provides the OS images **402-408** running in multiple logical partitions each a virtual copy of a console and operator panel. The interface to
10 the console is changed from an asynchronous teletype port device driver, as in the prior art, to a set of hypervisor firmware calls that emulate a port device driver. The hypervisor **510** encapsulates the data from the various OS images onto a message stream that is
15 transferred to a computer **580**, known as a hardware system console **580**.

Hardware system console **580** is connected directly to logically partitioned platform **500** as illustrated in **Figure 5**, or may be connected to logically partitioned
20 platform through a network, such as, for example, network **102** in **Figure 1**. Hardware system console **580** may be, for example, a desktop or laptop computer, and may be implemented as data processing system **200** in **Figure 2**. Hardware system console **580** decodes the message stream
25 and displays the information from the various OS images **402-408** in separate windows, at least one per OS image. Similarly, keyboard input information from the operator is packaged by the hardware system console, sent to logically partitioned platform **500** where it is decoded
30 and delivered to the appropriate OS image via the hypervisor **510** emulated port device driver associated

Docket No. AUS990938US1

with the then active window on the hardware system console **580**.

Those of ordinary skill in the art will appreciate that the hardware and software depicted in **Figure 5** may vary. For example, more or fewer processors and/or more or fewer operating system images may be used than those depicted in **Figure 5**. The depicted example is not meant to imply architectural limitations with respect to the present invention.

With reference now to **Figures 6A-6B**, high-level flowcharts illustrating exemplary processes, performed for example, in hypervisor **510**, for emulating a console and operator platform is depicted in accordance with the present invention. The operating systems, such as, for example, OS **402-408** in **Figure 4**, call the hypervisor through a single entry point. One thread of execution illustrated in **Figure 6A** gets data from a per partition buffer and sends data to the hardware system console while a separate thread of execution illustrated in **Figure 6B** receives data from the hardware system console.

In the first thread of execution depicted in **Figure 6A**, the hypervisor receives a request from an operating system to get or send data (step **601**). The hypervisor determines whether the request is a request to send or get data (step **602**). If the request is a request to send data, then the hypervisor determines from which OS image (partition) the received data originated (step **604**). The received data is then encapsulated onto a message stream (step **606**). The encapsulated data includes the message or information received from the OS as well as the

Docket No. AUS990938US1

identity of the OS. The hypervisor then sends the message stream to the hardware system console (step 608).

If the request is a request to get data, then the hypervisor determines which OS partition requested the data (step 610). Each partition is assigned a data buffer for storing data received from the hardware system console until retrieved by the partition's OS. Thus, the hypervisor determines whether the requesting partition's data buffer is empty (step 612). If the data buffers for the requesting partition is empty, then the hypervisor sends a NULL message to the requesting OS image indicating that there is no data from the hardware system console for the OS image to receive (step 616). If the data buffer is not empty, then the message data from the partition's data buffer is sent to the requesting OS image (step 614).

In the second thread of execution depicted in **Figure 6B**, the hypervisor receives and decodes data from the hardware system console (step 618). The hypervisor then places the decoded data into the buffer corresponding to the appropriate partition such that it may be retrieved and sent to the appropriate partition's OS image upon request (step 620).

With reference now to **Figure 7**, a high level flowchart illustrating an exemplary process on a hardware system console for presenting the information from the various OS images to an operator is depicted in accordance with the present invention. To begin, the hardware system console receives a message stream from the hypervisor (step 702). The hardware system console decodes the message stream (step 704) and determines to

Docket No. AUS990938US1

which OS image the received data corresponds (step 706). Next, the hardware system console determines which window within the display corresponds to the determined OS image (step 708) and displays the received data to an operator
5 in the window corresponding to the proper OS image (step 710).

With reference now to **Figure 8**, a high level flowchart illustrating an exemplary process on a hardware system console for sending messages to various ones of
10 multiple OS images running on a logically partitioned platform is depicted in accordance with the present invention. To begin, the hardware system console receives input from an operator from an input device, such as, for example, a keyboard (step 802). The
15 hardware system console then determines which OS image corresponds to the active window from which the input was received (step 804). The data input, along with the OS image it corresponds with, are encapsulated into a message stream (step 806). The message stream is then
20 sent to the hypervisor (step 808).

It is important to note that while the present invention has been described in the context of a fully functioning data processing system, those of ordinary skill in the art will appreciate that the processes of
25 the present invention are capable of being distributed in the form of a computer readable medium of instructions and a variety of forms and that the present invention applies equally regardless of the particular type of signal bearing media actually used to carry out the
30 distribution. Examples of computer readable media include recordable-type media such as a floppy disc, a

Docket No. AUS990938US1

hard disk drive, a RAM, and CD-ROMs and transmission-type media such as digital and analog communications links.

The description of the present invention has been presented for purposes of illustration and description,
5 but is not intended to be exhaustive or limited to the invention in the form disclosed. Many modifications and variations will be apparent to those of ordinary skill in the art. The embodiment was chosen and described in order to best explain the principles of the invention,
10 the practical application, and to enable others of ordinary skill in the art to understand the invention for various embodiments with various modifications as are suited to the particular use contemplated.
